the root lies near 10^{26}. One might thus think to specify convergence by a relative (fractional) criterion, but this becomes unworkable for roots near zero. To be most general, the routines below will require you to specify an absolute tolerance, such that iterations continue until the interval becomes smaller than this tolerance in absolute units. Usually you may wish to take the tolerance to be $\epsilon|\text{x}_1| + |\text{x}_2|/2$ where $\epsilon$ is the machine precision and $\text{x}_1$ and $\text{x}_2$ are the initial brackets. When the root lies near zero you ought to consider carefully what reasonable tolerance means for your function.

The following routine quits after 40 bisections in any event, with $2^{-40} \approx 10^{-12}$.

```fortran
FUNCTION rtbis(func,x1,x2,xacc)
INTEGER JMAX
REAL rtbis,x1,x2,xacc,func
EXTERNAL func
PARAMETER (JMAX=40)

Maximum allowed number of bisections.

Using bisection, find the root of a function func known to lie between x1 and x2.

The root, returned as rtbis, will be refined until its accuracy is \pm xacc.

INTEGER j
REAL dx,f,fmid,xmid
fmid=func(x2)
f=func(x1)
if(f*fmid.ge.0.) pause 'root must be bracketed in rtbis'
if(f.lt.0.)then
   Orient the search so that f>0 lies at x+dx.
   rtbis=x1
   dx=x2-x1
else
   rtbis=x2
   dx=x1-x2
endif
do 11 j=1,JMAX
   Bisection loop.
   dx=dx*.5
   xmid=rtbis+dx
   fmid=func(xmid)
   if(fmid.le.0.)rtbis=xmid
   if(abs(dx).lt.xacc .or. fmid.eq.0.) return
endo:
pause 'too many bisections in rtbis'
END
```

9.2 Secant Method, False Position Method, and Ridders’ Method

For functions that are smooth near a root, the methods known respectively as false position (or regula falsi) and secant method generally converge faster than bisection. In both of these methods the function is assumed to be approximately linear in the local region of interest, and the next improvement in the root is taken as the point where the approximating line crosses the axis. After each iteration one of the previous boundary points is discarded in favor of the latest estimate of the root.

The only difference between the methods is that secant retains the most recent of the prior estimates (Figure 9.2.1; this requires an arbitrary choice on the first iteration), while false position retains that prior estimate for which the function value
Figure 9.2.1. Secant method. Extrapolation or interpolation lines (dashed) are drawn through the two most recently evaluated points, whether or not they bracket the function. The points are numbered in the order that they are used.

Figure 9.2.2. False position method. Interpolation lines (dashed) are drawn through the most recent points that bracket the root. In this example, point 1 thus remains “active” for many steps. False position converges less rapidly than the secant method, but it is more certain.
9.2 Secant Method, False Position Method, and Ridders’ Method

Figure 9.2.3. Example where both the secant and false position methods will take many iterations to arrive at the true root. This function would be difficult for many other root-finding methods.

has opposite sign from the function value at the current best estimate of the root, so that the two points continue to bracket the root (Figure 9.2.2). Mathematically, the secant method converges more rapidly near a root of a sufficiently continuous function. Its order of convergence can be shown to be the “golden ratio” 1.618... so that

\[
\lim_{k \to \infty} |\epsilon_{k+1}| \approx \text{const} \times |\epsilon_k|^{1.618}
\] (9.2.1)

The secant method has, however, the disadvantage that the root does not necessarily remain bracketed. For functions that are not sufficiently continuous, the algorithm can therefore not be guaranteed to converge: Local behavior might send it off towards infinity.

False position, since it sometimes keeps an older rather than newer function evaluation, has a lower order of convergence. Since the newer function value will sometimes be kept, the method is often superlinear, but estimation of its exact order is not so easy.

Here are sample implementations of these two related methods. While these methods are standard textbook fare, Ridders’ method, described below, or Brent’s method, in the next section, are almost always better choices. Figure 9.2.3 shows the behavior of secant and false-position methods in a difficult situation.

FUNCTION rtflsp(func,x1,x2,xacc)
INTEGER MAXIT
REAL rtflsp,x1,x2,xacc,func
EXTERNAL func
PARAMETER (MAXIT=30) Set to the maximum allowed number of iterations.
Chapter 9. Root Finding and Nonlinear Sets of Equations

Using the false position method, find the root of a function $\text{func}$ known to lie between $x_1$ and $x_2$. The root, returned as $\text{rtflsp}$, is refined until its accuracy is $±x_{acc}$.

```
INTEGER j
REAL del,dx,f,fh,fl,swap,xh,xl
fl=func(x1)
fh=func(x2)  \quad \text{Be sure the interval brackets a root.}
if(f1*fh.gt.0.) pause 'root must be bracketed in rtflsp'
if(f1.lt.0.) then  \quad \text{Identify the limits so that } x_1 \text{ corresponds to the low side.}
  x1=x1
  xh=x2
else
  xl=x2
  xh=x1
  swap=fl
  fl=fh
  fh=swap
endif
dx=xh-xl
do : : j=1,MAXIT  \quad \text{False position loop.}
rtnflsp=xl+dx*fl/(fl-fh)  \quad \text{Increment with respect to latest value.}
f=func(rtflsp)
if(f1.lt.0.) then  \quad \text{Replace appropriate limit.}
  del=xl-rtflsp
  xl=rtflsp
  fl=f
else
  del=xh-rtflsp
  xh=rtflsp
  fh=f
endif
dx=xh-xl
if(abs(del).lt.xacc.or.f.eq.0.)return  \quad \text{Convergence.}
enddo : :  
pause 'rtflsp exceed maximum iterations'
END
```

```
FUNCTION rtsec(func,x1,x2,xacc)
integer MAXIT
REAL rtsec,x1,x2,xacc,func
EXTERNAL func
PARAMETER (MAXIT=30)  \quad \text{Maximum allowed number of iterations.}
Using the secant method, find the root of a function $\text{func}$ thought to lie between $x_1$ and $x_2$. The root, returned as $\text{rtsec}$, is refined until its accuracy is $±x_{acc}$.

INTEGER j
REAL dx,f,f1,swap,xl
f1=func(x1)
f=func(x2)
if(abs(f1).lt.abs(f))then  \quad \text{Pick the bound with the smaller function value as the most recent guess.}
  rtsec=x1
  x1=x2
  swap=f1
  f1=f
  f=swap
else
  x1=x1
  rtsec=x2
endif
do : : j=1,MAXIT  \quad \text{Secant loop.}
dx=(x1-rtsec)*f/(f-f1)  \quad \text{Increment with respect to latest value.}
x1=rtsec
f1=f
rtsec=rtsec+dx
END
```
Ridders’ Method

A powerful variant on false position is due to Ridders[1]. When a root is bracketed between \(x_1\) and \(x_2\), Ridders’ method first evaluates the function at the midpoint \(x_3 = (x_1 + x_2)/2\). It then factors out that unique exponential function which turns the residual function into a straight line. Specifically, it solves for a factor \(e^Q\) that gives

\[
    f(x_1) - 2f(x_3)e^Q + f(x_2)e^{2Q} = 0
\]

This is a quadratic equation in \(e^Q\), which can be solved to give

\[
    e^Q = \frac{f(x_3) + \text{sign}[f(x_2)]\sqrt{f(x_3)^2 - f(x_1)f(x_2)}}{f(x_2)}
\]

Now the false position method is applied, not to the values \(f(x_1), f(x_3), f(x_2)\), but to the values \(f(x_1), f(x_3)e^Q, f(x_2)e^{2Q}\), yielding a new guess for the root, \(x_4\). The overall updating formula (incorporating the solution 9.2.3) is

\[
    x_4 = x_3 + \frac{(x_3 - x_1)\text{sign}[f(x_1) - f(x_2)]f(x_3)}{\sqrt{f(x_3)^2 - f(x_1)f(x_2)}}
\]

Equation (9.2.4) has some very nice properties. First, \(x_4\) is guaranteed to lie in the interval \((x_1, x_2)\), so the method never jumps out of its brackets. Second, the convergence of successive applications of equation (9.2.4) is quadratic, that is, \(m = 2\) in equation (9.1.4). Since each application of (9.2.4) requires two function evaluations, the actual order of the method is \(\sqrt{2}\), not 2; but this is still quite respectably superlinear: the number of significant digits in the answer approximately doubles with each two function evaluations. Third, taking out the function’s “bend” via exponential (that is, ratio) factors, rather than via a polynomial technique (e.g., fitting a parabola), turns out to give an extraordinarily robust algorithm. In both reliability and speed, Ridders’ method is generally competitive with the more highly developed and better established (but more complicated) method of Van Wijngaarden, Dekker, and Brent, which we next discuss.

FUNCTION zriddr(func,x1,x2,xacc)
INTEGER MAXIT
REAL zriddr,x1,x2,xacc,func,UNUSED
PARAMETER (MAXIT=60,UNUSED=-1.11E30)
EXTERNAL func
C USES func

Using Ridders’ method, return the root of a function func known to lie between x1 and x2. The root, returned as zriddr, will be refined to an approximate accuracy xacc.
fl=func(x1)
fh=func(x2)
if((fl.gt.0..and.fh.lt.0.).or.(fl.lt.0..and.fh.gt.0.))then
  xl=x1
  xh=x2
zriddr=UNUSED
  do :: j=1,MAXIT
    xm=0.5*(xl+xh)
    fm=func(xm)
    s=sqrt(fm**2-fl*fh)
    if(s.eq.0.)return
    xnew=xm+(xm-xl)*(sign(1.,fl-fh)*fm/s)
    if (abs(xnew-zriddr).le.xacc) return
    zriddr=xnew
    fnew=func(zriddr)
    if (fnew.eq.0.) return
    if(sign(fm,fnew).ne.fm) then
      Bookkeeping to keep the root bracketed on next iteration.
      xl=xm
      fl=fm
      xh=zriddr
      fh=fnew
    else if(sign(fl,fnew).ne.fl) then
      xh=zriddr
      fh=fnew
    else if(sign(fh,fnew).ne.fh) then
      xl=zriddr
      fl=fnew
    else
      pause 'never get here in zriddr'
    endif
    if(abs(xh-xl).le.xacc) return
  enddo ::
  pause 'zriddr exceed maximum iterations'
else if (fl.eq.0.) then
  zriddr=x1
else if (fh.eq.0.) then
  zriddr=x2
else
  pause 'root must be bracketed in zriddr'
endif
return
END
